

SPECIFICATION

TITLE OF THE INVENTION

Plasma Processing Method and Apparatus

5 BACKGROUND OF THE INVENTION

The present invention relates to plasma processing method and apparatus which can be used for thin-film circuit formation methods in semiconductor and thin-film display industries thin-film circuit formation and, in particular, which allow transistor devices to be formed on
10 such highly insulative substrates as glass, quartz, compound semiconductors. The present invention also relates to plasma processing method and apparatus capable of efficiently reducing occurrence of device damage and
15 device breakage that otherwise might occur when a processing-object substrate, which has already been in a charge-stored state since before plasma processing, is subjected to plasma processing, in such a charge-stored state.

20 In recent years, in thin-film device manufacturing fields, there has been a growing demand for process simplification and manufacturing-method modifications toward those which involve less environmental loads, from the viewpoints of manufacturing cost and
25 environmental protection. Thus, there are desires for

advancement from conventional engineering methods using chemicals toward engineering methods, as well as apparatuses, in which thin-film processing is performed by applying plasma.

5 However, such thin-film devices as shown above are manufactured through a wide variety of manufacturing steps, including, for example, a step of heat treatment, a step of water washing treatment, and a step using the plasma application. As a result of this, there are
10 possibilities, at all times, of occurrence of electric charge storage on the top and bottom of the processing-object substrate from various factors.

 Thin-film processing and apparatuses using the application of plasma, which include the steps of
15 generating plasma in a vacuum, alienating process gas, and performing processing in combination of physical and chemical reactions by ions and radicals, would involve generation of much larger amounts of charges on the processing-object substrate.

20 With regard to the charges generated in large amounts, although a dielectric film for insulating metal films is formed as a thin film, involving a threshold value for withstand voltage in terms of structure of thin-film circuits, yet there are cases where if the processing-
25 object substrate is charged and electrified with such

charges as the threshold value would be exceeded, a breakdown of the dielectric film would occur, making it impossible to make up a thin-film circuit. For this reason, it has conventionally been discussed and practiced to use a plasma that would be charged on the processing-object substrate as less as possible, or to reduce the given charges by devising plasma process measures.

Hereinbelow, a typical form of dry etching apparatus is explained with reference to Fig. 3.

Reference numeral 101 denotes a plasma processing vessel for performing dry etching process, 101a denotes a process gas and inert-gas introducer, 102 denotes an electrode having functions of generating a plasma and serving for placing thereon a processing-object substrate 112, 103 denotes an evacuator, 104 denotes a vacuum transfer vessel for putting the processing-object substrate 112 into and out of the plasma processing vessel in a state of vacuum pressure, 104a denotes an evacuator, 104b denotes an inert-gas introducer, 105 denotes a gate door which serves as a partition wall between the plasma processing vessel 101 and the vacuum transfer vessel 104 and which has an opening/closing mechanism, 106 denotes a vacuum conveyance mechanism, 106a denotes a lift pin which is interlocked with the vacuum conveyance mechanism 106 and which operates for placing the processing-object substrate

112 onto the electrode 102, 107 denotes a load lock vessel capable of performing an operation of reducing the internal pressure of the vessel from atmospheric to vacuum state and, conversely, an operation of pressurizing the vessel from vacuum to atmospheric state, 107a denotes an evacuator, 107b denotes an inert-gas introducer, 108 denotes a gate door which serves as a partition wall between the vacuum transfer vessel 104 and the load lock vessel 107 in a vacuum state and which has an opening/closing mechanism, 109 denotes a gate door for holding the load lock vessel 107 in a vacuum state, 110 denotes a substrate storage device in which processing-object substrates 112 are stored, and 111 denotes an atmospheric conveyance mechanism for taking a processing-object substrate 112 out of the substrate storage device 110 and transferring the substrate 112 to the load lock vessel 107.

With respect to the dry etching apparatus constructed as shown above, its operation is explained below.

First, the processing-object substrate 112 is taken out of the substrate storage device 110 by the atmospheric conveyance mechanism 111, inert gas is purged from the inert-gas introducer 107b to the load lock vessel 107 to obtain an atmospheric state, the gate door 109 is opened, and the processing-object substrate 112 is conveyed

transferred to the load lock vessel 107 by the atmospheric conveyance mechanism 111.

Subsequently, the gate door 109 is closed, and in the load lock vessel 107, the operation of the inert-gas introducer 107b is halted and the load lock vessel 107 is evacuated from the evacuator 107a. After the evacuation to a specified pressure is completed, the gate door 108 is opened. The vacuum transfer vessel 104 is normally held in a vacuum state by the evacuator 104a operating for evacuation at all times. The processing-object substrate 112 placed on the load lock vessel 107 is taken out by the vacuum conveyance mechanism 106 and transferred to the vacuum transfer vessel 104, and the gate door 108 is closed.

The evacuator 103 provided at the plasma processing vessel 101 is normally performing the evacuation operation, so that the vessel 101 is normally held in the vacuum state. The gate door 105 is opened, and the processing-object substrate 112 present on the vacuum conveyance mechanism 106 within the vacuum transfer vessel 104 is transferred to the electrode 102 of the plasma processing vessel 101. After the processing-object substrate 112 is placed onto the lift pins 106a, the gate door 105 is closed, and the lift pins 106a move down so that the processing-object substrate is placed onto the electrode 102. After that, plasma processing is carried

out.

Subsequent to completion of the plasma processing, after performing a process which is so called charge-neutralizing process by such gas as N_2 or O_2 and which is to neutralize or remove charges electrified on the processing-object substrate 112 by changing the plasma generation area by pressure or power, or during this process, the lift pins 106a move up, so that the processing-object substrate 112 is lifted.

Thereafter, the gate door 105 is opened, and the processing-object substrate 112 present on the lift pins 106a within the plasma processing vessel 101 is taken out of the plasma processing vessel 101 and transferred into the vacuum transfer vessel 104 by the vacuum conveyance mechanism 106.

In this case, the evacuator 103 of the plasma processing vessel 101 performs an evacuation operation so that the reaction product after the plasma processing does not flow into the vacuum transfer vessel 104. The gate door 105 is closed, then the gate door 108 is opened, the processing-object substrate 112 is transferred to the load lock vessel 107 by the vacuum conveyance mechanism 106, and the gate door 108 is closed. The evacuator 107a within the load lock vessel 107 is halted, and the inert gas is purged from the inert-gas introducer 107b, where the interior of

the load lock vessel 107 is changed from vacuum pressure to atmospheric pressure state. Then, the gate door 109 is opened, and the processing-object substrate 112 present in the load lock vessel 107 is taken out and stored into the substrate storage device 110 by the atmospheric conveyance mechanism 111 (see Japanese Unexamined Patent Publication No. 07-106314, and Japanese Patent Nos. 3227812, and 3170849).

However, in the processes subsequent to the completion of the plasma processing of the processing-object substrate 112 in the plasma processing vessel 101, the processes including the steps of, after completion of the charge-neutralizing process, opening the gate door 105, taking out the processing-object substrate 112 present on the electrode 102 within the plasma processing vessel 101 from within the plasma processing vessel 101 and then transferring the processing-object substrate 112 into the vacuum transfer vessel 104 by the vacuum conveyance mechanism 106, potential values of the residual charges remaining on the surface of the processing-object substrate 112 exhibit such behavior as shown in Fig. 4B.

The charges electrified on the surface of the processing-object substrate 112 after the plasma processing show the maximum potential value at the passage through the gate door 105, and while keeping a high voltage state still

thereafter, the processing-object substrate 112 is placed onto the vacuum transfer vessel 104. There is an issue, in this case, that dielectric breakdown may occur when the charging potential that varies during the transfer of the processing-object substrate 112 in the vacuum has exceeded a withstand voltage threshold 102a of the dielectric film formed on the processing-object substrate 112.

This is limited to cases where, as shown in Fig. 5, there exists a distance d that satisfies the following formula (Eq. 1) during the transfer of the processing-object substrate 112 in transitions from the charges of $+Q$ of the surface of the electrode 102, with opposed to and polarized from the charges of $-Q$ electrified on the surface of the processing-object substrate 112 (at this time point, the distance d between the rear face of the processing-object substrate 112 and the top surface of the electrode 102 is infinitely large so that the formula (Eq. 1) is not applicable), to the bottom face of the plasma processing vessel, to the bottom face of the gate door 105, and to the bottom face of the vacuum transfer vessel 104:

$$-Q = C_g \times V_g = \epsilon \times (S/d) \times V_g$$

.....(Eq. 1): Basic formula for capacitors, wherein C_g : capacitor capacity at the gap of distance d , V_g : potential difference at the gap of distance d , S : area, d : distance, ϵ : dielectric constant. In Fig. 5, V_{gmax} is a

potential at the maximum gap at the distance d .

As can be understood from the above equation (Eq. 1), the reason could be attributed to the possibility that V_g may increase upon arrival at a region (d_{min}) which is
5 affected by d (distance).

Of course, it can easily be presumed that the surface potential of the processing-object substrate 112 increases to the most at the moment when the processing-object substrate 112 separates from the electrode 102. At
10 this time point, a portion of the processing-object substrate 112 has passed through the gate door 105, so that even if occurrence of the dielectric breakdown is avoided, the surface potential can abnormally increase only at a portion of the processing-object substrate 112. On this
15 ground, it is inferred that the dielectric breakdown can occur at that portion.

Also, without occurrence of the dielectric breakdown, a thin film bearing an active state, which is generally called damage, formed on the processing-object
20 substrate 112, would cause the composition of the thin film interior to be changed along with local increases in the charges, thus making a factor for deteriorations in characteristics and performance of the thin film.

In common vacuum mass-production equipment, the
25 gate door is manufactured as small as possible in order to

reduce the pressure loss upon opening and closing of the gate door. At the point where the processing-object substrate 112 passes through the gate door 105, the distance between the processing-object substrate 112 and the gate door 105 becomes an extremely small one, that is, the processing-object substrate 112 and the gate door 105 become infinitely close to each other, the distance falling within a range subject to influences of the basic formula for electrostatic capacity. The potential V_g in a portion of the processing-object substrate 112 shows a value higher than that on the electrode 102.

In conjunction with the above description, since there are no places where the accumulated charges are discharged as far as the processing-object substrate 112 is transferred in the vacuum, which makes the processing-object substrate 112 kept bearing charges at a very high level until coming to an atmospheric state, it can occur that portions other than the gate door 105 become more influenced by the equation (Eq. 1), depending on the configuration of mass-production equipment.

In view of these and other issues of the prior art, an object of the present invention is to provide plasma processing method and apparatus capable of reducing an amount of charges on a processing-object substrate, which varies during transfer of the processing-object

substrate subsequent to its plasma processing.

SUMMARY OF THE INVENTION

In order to achieve the above object, according
5 to a first aspect of the present invention, there is
provided a plasma processing method for forming, under a
reduced pressure, a thin-film circuit on a processing-
object substrate which is to be subjected to plasma
processing, the method comprising:

10 before performing plasma processing on the
processing-object substrate, subjecting the processing-
object substrate to a charge-neutralization-use plasma in
gas composed mainly of inert gas so that charges
electrified on the processing-object substrate are
15 neutralized.

According to a second aspect of the present
invention, there is provided the plasma processing method
as defined in the first aspect, wherein the inert gas is at
least one gas selected from among Ar, He, N₂, H₂, and
20 vaporized H₂O gas.

According to a third aspect of the present
invention, there is provided the plasma processing method
as defined in the first or second aspect, wherein top and
bottom surfaces of the processing-object substrate are
25 simultaneously subjected to the plasma in the inert gas.

According to a fourth aspect of the present invention, there is provided a plasma processing apparatus comprising:

a vacuum vessel;

5 a first electrode for placing thereon a processing-object substrate which is to be subjected to plasma processing;

10 a lift pin for holding thereon the processing-object substrate and placing the substrate onto the first electrode;

a conveyance system for transferring the processing-object substrate to the lift pin;

a second electrode disposed so as to confront the first electrode;

15 an evacuator for evacuating interior of the vacuum vessel;

a process-gas introducer for introducing process gas into the vacuum vessel;

20 a high-frequency power supply for, in a state that the process gas is introduced into the vacuum vessel by the process-gas introducer while the interior of the vacuum vessel is evacuated by the evacuator, applying a high-frequency power to the first electrode so that a plasma is generated in the vacuum vessel;

25 an inert-gas introducer for introducing inert gas

into the vacuum vessel before the processing-object substrate is subjected to plasma processing with the process gas introduced into the vacuum vessel by the process-gas introducer; and

5 a control unit for, before execution of the plasma processing on the processing-object substrate, controlling the high-frequency power supply to generate an electrified charge-neutralization-use plasma in the inert gas.

10 According to a fifth aspect of the present invention, there is provided the plasma processing apparatus as defined in the fourth aspect, wherein the control unit controls operation of the lift pin so that before the placement of the processing-object substrate
15 onto the first electrode, top-and-bottom surfaces of the processing-object substrate are simultaneously subjected to the electrified charge-neutralization-use plasma by the inert gas.

 According to the present invention, there can be
20 provided the plasma processing method and apparatus in which before execution of the plasma processing on the processing-object substrate, the processing-object substrate is subjected to the charge-neutralization-use plasma composed mainly of inert gas so that initial charges
25 electrified on the processing-object substrate are

neutralized immediately before the plasma processing, by which the top-and-bottom surfaces of the processing-object substrate as well as the top surface of the electrode are made equal in potential to each other, thus making it possible to prevent plasma damage that otherwise could occur after the plasma processing.

Generally, it has never been conceived hitherto to perform plasma discharge before the plasma processing because of a possibility that reaction products or the like deposited on the wall surfaces of the plasma processing chamber might fly around to stick to the processing-object substrate, resulting in particle failures. However, in recent years, there has been a tendency that the rate of the particle failures is exceeded by the rate of failures that occur when the processing-object substrate, which has been charged during its transfer, is placed onto an electrode that has been charged at a different potential. Therefore, in the present invention, while reaction products or the like deposited on the wall surfaces of the plasma processing chamber are prevented from flying around as much as possible with a view to avoiding particle failures, a minimum necessary plasma is generated so that the top-and-bottom two surfaces of the processing-object substrate and the top surface of the electrode are made equal in potential to each other. In other words, by

generating the minimum necessary plasma, i.e. a charge-neutralization-use plasma, that allows the top-and-bottom two surfaces of the processing-object substrate and the top surface of the electrode to be made equal in potential to each other, it becomes possible to more effectively prevent plasma damage that otherwise could occur after the plasma processing.

BRIEF DESCRIPTION OF THE DRAWINGS

These and other aspects and features of the present invention will become clear from the following description taken in conjunction with the preferred embodiments thereof with reference to the accompanying drawings, in which:

Fig. 1A is a plan view of outlined configuration of a plasma processing apparatus according to a first embodiment of the present invention;

Fig. 1B is a side view of outlined configuration of a plasma processing vessel of the plasma processing apparatus according to the first embodiment of the present invention;

Fig. 2 is a side view of outlined configuration of the plasma processing apparatus according to the first embodiment;

Fig. 3 is an outlined structural view of a

conventional plasma processing apparatus;

Figs. 4A and 4B are an outlined structural view of the conventional plasma processing apparatus and a graph showing the relationship between the position of the processing-object substrate and the surface charging value in the outlined structure of the conventional plasma processing apparatus, respectively; and

Fig. 5 is an outlined view of the mechanism of the increase of the surface potential (voltage) of the processing-object substrate.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Before the description of the present invention proceeds, it is to be noted that like parts are designated by like reference numerals throughout the accompanying drawings.

Hereinbelow, embodiments of the present invention are described in detail with reference to the accompanying drawings.

A plasma processing method and apparatus according to a first embodiment of the present invention are explained with reference to the drawings.

Here are described typical dry etching apparatus and method for the plasma processing method and apparatus of the first embodiment are explained with reference to

Figs. 1A and 1B and Fig. 2. Reference numeral 1 denotes a plasma processing vessel (one example of plasma processing chamber) for dry etching, 1a denotes an inert-gas introducer (introducing device) for introducing inert gas into the plasma processing vessel 1 at the time of neutralization of electrified charges before plasma processing, and 1b denotes a process-gas introducer (introducing device) for introducing process gas into the plasma processing vessel 1 at the time of plasma processing. Also, numeral 2 denotes an electrode having a function of generating a plasma and serving for placing thereon a processing-object substrate 12 that is to be subjected to plasma processing, 2a denotes a high-frequency power supply, 2b denotes a grounded counter electrode, and 2c denotes a matching box which is an impedance matching circuit interposed between the high-frequency power supply 2a and the electrode 2. Further, numeral 3 denotes an evacuator (evacuating device) such as a pump for reducing the internal pressure of the plasma processing vessel 1, 4 denotes a vacuum transfer vessel (one example of vacuum transfer chamber) provided adjacent to the plasma processing vessel 1 so as to allow the processing-object substrate 12 to be put into and out of the plasma processing vessel 1 in a vacuum pressure state, 4a denotes an evacuator (evacuating device) such as a pump for

reducing the internal pressure of the vacuum transfer vessel 4 as with the plasma processing vessel 1, 4b denotes an N₂ gas introducer (introducing device) for introducing N₂ gas into the vacuum transfer vessel 4, 5 denotes a gate door which serves as a partition wall between the plasma processing vessel 1 and the vacuum transfer vessel 4 and which has an opening/closing mechanism for opening and closing the door 5, and 6 denotes a vacuum conveyance mechanism for conveying the processing-object substrate 12 between the plasma processing vessel 1 and the vacuum transfer vessel 4 which are both in a vacuum state. Also, 6a denotes a lift pin which is used to separate the processing-object substrate 12 and the electrode 2 from each other in the plasma processing vessel 1, 6b denotes a lift pin up/down device such as a motor or an air cylinder for lifting and lowering all of the lift pins 6a, 7 denotes a load lock vessel (one example of load lock chamber) capable of performing an operation of reducing the internal pressure of the vessel from atmospheric to vacuum state and, conversely, an operation of pressurizing the vessel from vacuum to atmospheric state, 7a denotes an evacuator (evacuating device) such as a pump for performing the above-mentioned pressure-reducing operation, and 7b denotes an N₂ gas introducer (introducing device). Further, 8 denotes a gate door which serves as a partition wall

between the vacuum transfer vessel 4 and the load lock vessel 7 and which has an opening/closing mechanism for opening and closing the door 8, 9 denotes a gate door for maintaining the load lock vessel 7 in a vacuum state, and 5 10 denotes a substrate storage device in which processing-object substrates 12 are stored. Numeral 11 denotes an atmospheric conveyance mechanism such as a robot arm for taking a processing-object substrate 12 out of the substrate storage device 10 and transferring the substrate 10 12 to the load lock vessel 7. Also, numeral 1000 denotes a control unit for controlling operations of the inert-gas introducer 1a, the process-gas introducer 1b, the high-frequency power supply 2a, the matching box 2c, the evacuator 3, the evacuator 4a, the N₂ gas introducer 4b, 15 the gate door 5, the vacuum conveyance mechanism 6, the lift pin up/down device 6b, the evacuator 7a, the N₂ gas introducer 7b, the gate door 8, the gate door 9, the substrate storage device 10, and the atmospheric conveyance mechanism 11, respectively.

20 With respect to the dry etching apparatus constructed as shown above, its operation is explained below. The following operation is controlled by the control unit 1000.

25 First, the processing-object substrate 12 is taken out of the substrate storage device 10 by the

atmospheric conveyance mechanism 11, N₂ gas is purged from the inert-gas introducer 7b to the load lock vessel 7 to obtain an atmospheric state, the gate door 9 is opened, and the processing-object substrate 12 is conveyed to the load lock vessel 7 by the atmospheric conveyance mechanism 11. Subsequently, the gate door 9 is closed, and in the load lock vessel 7, the operation of the inert-gas introducer 7b is halted and the load lock vessel 7 is evacuated from the evacuator 7a. After the evacuation to a specified pressure is completed, the gate door 8 is opened.

The vacuum transfer vessel 4 is normally held in a vacuum state by the evacuator 4a operating for evacuation at all times. The processing-object substrate 12 placed on the load lock vessel 7 is taken out by the vacuum conveyance mechanism 6 and transferred to the vacuum transfer vessel 4, and the gate door 8 is closed. The evacuator 3 provided at the plasma processing vessel 1 is normally performing the evacuation operation, so that the interior of the plasma processing vessel 1 is normally held in the vacuum state. The gate door 5 is opened, and the processing-object substrate 12 present on the vacuum conveyance mechanism 6 within the vacuum transfer vessel 4 is transferred onto the lift pins 6a of the plasma processing vessel 1, where the gate door 5 is closed.

In the state that the processing-object substrate

12 is held on the lift pins 6a, the inert gas is introduced from the inert-gas introducer 1a into the plasma processing vessel 1, and with a high-frequency power applied from the high-frequency power supply 2a to the electrode 2, there is generated an electrified charge-neutralization-use weak (faint) plasma which is generated in gas composed mainly of inert gas and which is of such a level that the processing-object substrate 12 will not be etched and that a thin film will not be formed thereon. That is, in this case where, with an inert gas such as N_2 gas introduced from the inert-gas introducer 1a, the interior of the plasma processing vessel 1 adjusted to about 40 Pa by the evacuator 3, and with the application of a high-frequency power of 0.1 W/cm^2 from the high-frequency power supply 2a to the electrode 2, the electrified-charge-neutralization-use weak plasma is generated for five seconds, by which the preprocessing charge neutralization on the top-and-bottom two surfaces of the processing-object substrate 12 and the top surface of the electrode 2 is performed so that the top-and-bottom two surfaces of the processing-object substrate 12 and the top surface of the electrode 2 are made equal in potential to each other. Thereafter, the lift pins 6a are lowered by the drive of the lift pin up/down device 6b, and the processing-object substrate 12 is placed onto the electrode 2. Thus, the introduction of the inert gas from the inert-

gas introducer 1a is halted, and meanwhile the process gas is introduced from the process-gas introducer 1b, where a desired plasma processing is performed on a wafer of 8 inches as an example of the processing-object substrate 12 with a high-frequency power of, for example, 100 to 150 W/cm² applied from the high-frequency power supply 2a to the electrode 2. For the desired plasma processing, a chlorine-based gas is introduced as the process gas for metal-based thin films of the processing-object substrates 12, a fluorine-based gas is introduced as the process gas for the processing-object substrate 12 of silicon, and an oxygen-based gas is introduced as the process gas for plasma processing of resist or the like of the processing-object substrate 12, where the desired plasma processing, such as etching, thin film formation, or resist removal, is performed.

It is noted here that the high-frequency power to be used for the generation of the weak plasma, which is generated in the gas composed mainly of inert gas and which is of such a level that the processing-object substrate 12 will not be etched and that a thin film will not be formed thereon, is preferably not more than 1/3 of the high-frequency power for the plasma processing, or 0.1 to 1.0 W/cm². The time duration of the high-frequency power is preferably not more than 10 seconds.

The inert gas is at least one selected from among Ar, He, N₂, H₂, and vaporized H₂O.

Without a limitation to the construction that the lift pins 6a are lowered after execution of the pre-process charge neutralization of the processing-object substrate 12 and the electrode 2, it may also be constructed that the lift pins 6a are lowered while the pre-process charge neutralization of the processing-object substrate 12 and the electrode 2 is being executed.

In cases where the above-described preprocessing by weak plasma was executed and not, charging potential values on the processing-object substrates 12 were measured in the plasma processing vessel 1 under a vacuum with a noncontact type surface potential electrometer. As a result, charges accumulated on the surface of the processing-object substrate 12 are as shown in Table 1.

Table 1:

	Before desired plasma processing	After desired plasma processing
Prior art (without pre-process charge neutralization by plasma)	Large variations (- tens of volts through + tens of volts)	- tens of volts through hundreds of volts (reducible to about - tens of volts by charge-neutralizing removing process, but damage involved)
Present invention (with pre-process charge neutralization by plasma)	Small variations (- a few volts through + a few volts)	- tens of volts

Hitherto, it has been considered that plasma damage or dielectric breakdown would occur due to charges generated and given from the plasma during a desired plasma processing.

However, from the evaluation results on which the present invention is based, it can be considered that, due to the fact that charges electrified only on the top side of the processing-object substrate 12 are added as a result of the desired plasma processing to the charges that have been accumulated since before the processing and that are present on top and bottom of the processing-object substrate 12, the balance of charges between the top and bottom of the processing-object substrate 12 is disturbed, which would adversely affect the devices on the thin-film

circuit, thus causing the generation of plasma damage or dielectric breakdown.

The charges that the processing-object substrate 12 has had since early stages can be presumed to be charges due to heat treatment or water washing treatment in the preprocessing or to frictional electrification during the transfer of the processing-object substrate 12 in the atmospheric air, as well as charges due to frictional electrification during the transfer from the substrate storage device 10 to the load lock vessel 7 and exhaustion from the atmospheric pressure to the vacuum state.

Accordingly, by performing the charge-neutralizing process as a pre-process on the top and bottom surfaces of the processing-object substrate 12 and the top surface of the electrode 2 at the same time with a weak plasma immediately before the desired plasma processing is performed, the charges on the top and bottom of the processing-object substrate 12 and the top surface of the electrode 2 are electrically eliminated so that the top-and-bottom two surfaces of the processing-object substrate 12 and the top surface of the electrode 2 are made equal in potential to each other. Thus, plasma damage that could occur after the plasma processing, such as occurrence of plasma damage or dielectric breakdown on the devices on the thin-film circuit, can effectively be prevented.

Thereafter, the lift pins 6a are lifted by the drive of the lift pin up/down device 6b, and the processing-object substrate 12 is separated from on the electrode 2. Then, the gate door 5 is opened, and the
5 processing-object substrate 12 present on the lift pins 6a in the plasma processing vessel 1 is taken out of the plasma processing vessel 1 and transferred into the vacuum transfer vessel 4 by the vacuum conveyance mechanism 6.

Further, the damage suppression effect is
10 fulfilled to more extent by performing, after completion of the plasma processing, a process step of eliminating the charges electrified on the top-and-bottom two surfaces of the processing-object substrate 12 and the top surface of the electrode 2 in the charge-neutralizing process by such
15 gas as N_2 or O_2 .

Thereafter, the N_2 gas introducer 4b is halted, the gate door 5 is closed, the evacuator 4a is operated, the interior of the vacuum transfer vessel 4 is evacuated to a specified pressure or lower, and the interior of the
20 plasma processing vessel 1 as well is evacuated to a specified pressure or lower by the evacuator 3. Subsequently, the gate door 8 is opened, and the processing-object substrate 12 is transferred to the load lock vessel 7 by the vacuum conveyance mechanism 6, where
25 the gate door 8 is closed. The evacuator 7a in the load

lock vessel 7 is halted, the inert gas is purged from the inert-gas introducer 7b, where the interior of the load lock vessel 7 is changed from vacuum pressure to atmospheric pressure state. Then, the gate door 9 is
5 opened, and the processing-object substrate 12 present in the load lock vessel 7 is taken out and stored into the substrate storage 10 device by the atmospheric conveyance mechanism 11.

The embodiment of the present invention has been
10 described on a parallel-plate RIE plasma processing system. However, even if this system is replaced by such a plasma processing system as ICP, ECR, and PE system, the same effects can be obtained.

Also when a processing vessel for exclusive use
15 of preprocessing for generating the electrified charge-neutralization-use plasma is disposed independently of the plasma processing vessel 1, or when the preprocessing is performed with such a vessel as the vacuum transfer vessel 4, the same effects can be obtained.

20 By properly combining arbitrary embodiments of the aforementioned various embodiments, the effects owned by each of them can be made effectual.

Although the present invention has been fully described in connection with the preferred embodiments
25 thereof with reference to the accompanying drawings, it is

to be noted that various changes and modifications are
apparent to those skilled in the art. Such changes and
modifications are to be understood as included within the
scope of the present invention as defined by the appended
5 claims unless they depart therefrom.
